It hardly makes a difference the decision is already made but. The infrastructure and cost of most of the infrastructure is decades old. The current problem is a population increase that has no resources to back it up. ie capacity in the existing dams or infrastructure to support it . The answer isn't to increase costs for a bloated and outdated management system. But too increase water storage to meet the new demand on the resource ie water. Not to price the use of water to a point where it's use is uneconomic or practical. You can't increase the amount of sheep at the bucket and think they all will live. You will dismiss this as simplistic but in a dry country the right answer is some time the easiest.
